Abstract. The model of Stochastic Petri nets (SPN) with a product form solution ($\Pi$-net) is a class of nets for which there is an analytic expression of the steady state probabilities w.r.t. markings, as for product form queueing networks w.r.t. queue lengths. In this paper, we prove new important properties of this kind of nets. First we provide a polynomial time (w.r.t. the size of the net structure) algorithm to check whether a SPN is a $\Pi$-net. Then, we give a purely structural characterization of SPN for which a product form solution exists regardless of the particular values of probabilistic parameters of the SPN. We call such nets $\Pi$-nets. We also present untimed properties of $\Pi$-nets and $\Pi$-nets such like liveness, reachability, deadlock-freeness and characterization of reachable markings. The complexity of the reachability and the liveness problems is also addressed for $\Pi$-nets and $\Pi$-nets. These results complement previous studies on these classes of nets and improve the applicability of Product Form solutions.

1 Introduction

Stochastic Petri nets (SPNs) are a powerful tool for modelling and evaluating the performance systems involving concurrency, non-determinism, and synchronisation, such as parallel and distributed systems, communication networks, etc. The stochastic semantics of SPN have been proven to be a Continuous Time Markov Chain and steady state analysis can thus be expressed as the solution of a system of equilibrium equations, one for each possible marking of their state space. The major problem in the computation of performance measures using SPNs is the size of the reachability set of these models that increases exponentially both with the number of tokens in the initial marking and with the number of places in the net. As a consequence, the dimension of this reachability set and the time complexity of the solution procedure preclude, in the general

* At time of writing, P. Moreaux was visiting professor at the Dipartimento di Informatica, Università di Torino
case, the direct exact numerical evaluation of many interesting models. To cope
with this problem, we can first accept non exact performance measures. The
two main approaches developed in this area are discrete-event simulation and
approximate methods. Bounds computation methods provide more reliable in-
formation about the the performance indices. However, if we wish to obtain the
exact values of performance measures, then we may improve numerical methods
solving the underlying mathematical problem (linear or differential systems of
equations) and/or we may relate the structure of the model to the properties of
these underlying mathematical objects.

One successful approach in this last direction is the product form analysis
(PFA) for Queueing Networks (QN), that is the expression of basic performance
indices of QN, such as steady state probabilities, mean throughputs, utilization,
etc., as functions of the model parameters (service rates, routing probabilities,
properties of the service stations, etc.). The first structural property involved in
PFA is obviously the setting up of the model as a collection of service stations
bounded with paths taken by "clients". From this structure, PF solutions may
be proven for several classes of QN by examination of sets of some kind of "local
balance equations", for instance equations established for each station. Second,
specific descriptions of the state space of PF-QN lead to important relations. For
instance, the convolution algorithms [21] and the Mean Value Analysis (MVA)
method [4] are based upon recursive relations between models with state spaces
with different number of clients. Unfortunately, (the standard version of) PF-QN
offer limited possibilities for what concerns synchronization between clients activities. This situation was one of the main motivations in the study of Stochastic
Petri Nets (SPN) with a Product form solution (PF-SPN). First results about
PF-SPN were established in [15] based on the structure of the reachability graph
of the net. Recently, several authors proposed structural sufficient conditions for
a Petri net to be a PF-SPN. These results are summarized in Section 2. The
present paper supplements previous results for PF-SPN regarding four import-
ant issues.

**Membership Problem for SPN with PF solution** As we will see in Section
2, a straightforward verification procedure for deciding whether a given SPN has
a PF solution requires the computation of all minimal T-semiflows of the marked
net (T-semiflows are structural invariants of Petri nets (PN), see Section 2). It
is however known that the number of minimal T-semiflows can be exponential
in the number of transitions (e.g., [17]). In fact, we establish a polynomial time
algorithm to decide whether a SPN has a PF solution.

**Rate independent structural characterization of PF-SPN** Previous criteria
for PF-SPN have two drawbacks: they are only sufficient conditions, and
they involve properties of the rates of the transitions of the net. We present
a necessary and sufficient structural condition on nets to admit a PF solution
whatever the rates of its transitions. Hence we prove a rate-independent struc-
tural characterization of PF-SPN. Moreover, this criterion can be checked in
polynomial time.

**Untimed properties of PF-SPN** We investigate untimed properties for the
class of PF-SPN. Since many results (deadlock-freeness, liveness, etc.) have been
established for several known classes of PN, it can be valuable to point out the
relation between PF-SPN and these classes.

Reachability Set properties Efficient numerical solutions for PF-SPN re-
quire to characterize subsets of reachable markings. It is hence important to
have a structural criterion for reachable markings (e.g., a method based on the
minimal P-semiflows, a method based on the net state equation, etc.). We present
new results about these possible criteria.

The organization of the paper is the following: in Section 2, we review SPN
and previous results about H-nets. Section 3 presents the verification pro-
cept for PF-SPN and a series of results about the class of PF-SPN in relation to
other classes of Petri nets. In Section 3.3 we define the new class, T ̃-nets, of PF-
SPN corresponding to rate independent criteria for a PF solution together with
globally dependent rates. Untimed properties of H-nets are studied in Section
4. The conclusion summarizes results presented in the paper.

2 Background and notations

2.1 Stochastic Petri nets

One may find introductory presentations of Petri net concepts for instance in
[19, 20, 26]. We remind the reader only with definitions necessary to understand
product form results for stochastic Petri nets.

A marked stochastic Petri net is a 5-tuple \( SPN = (\mathcal{P}, \mathcal{T}, W, Q, m_0) \), where
\( \mathcal{P} \) and \( \mathcal{T} \) are disjoint sets of places and transitions (with \( |\mathcal{P}| = np \) and \( |\mathcal{T}| = nt \)),
\( W := (\mathcal{P} \times \mathcal{T}) \cup (\mathcal{T} \times \mathcal{P}) \rightarrow \mathbb{N} \) defines the weighted flow relation if \( W(i, j) > 0 \)
(resp. \( W(i, j) > 0 \)) then we say that there is an arc from \( t_j \) to \( p_i \), with weight \( W(j, i) \) or
multiplicity \( W(j, i) \) (resp. there is an arc from \( p_i \) to \( t_j \) with weight \( W(i, j) \)).
\( Q \) is the set of transition firing rates drawn from exponential distributions, and
\( m_0 \) is the initial marking.

For a given transition \( t_j \in \mathcal{T} \), its preset and postset are given by \( \bullet t_j = \{ p_i \mid W(i, j) > 0 \} \) and \( t_j \bullet = \{ p_i \mid W(j, i) > 0 \} \), respectively. In the same manner we can define the preset and postset of a given place.

For any transition \( t_j \), from the weighted flow relation we can define the input
vector \( i(t_j) = [W(1, j), W(2, j), \ldots, W(|\mathcal{P}|, j)] \) and the output vector \( o(t_j) = [W(j, 1), W(j, 2), \ldots, W(j, |\mathcal{P}|)] \). From the weighted flow relation we can also
define the incidence matrix \( C \) with entries \( C[i, j] = W(j, i) - W(i, j) \).

A transition \( t_j \) is enabled in a marking \( m \) iff \( m \geq i(t_j) \). Being enabled, \( t_j \) may occur (or fire) yielding a new marking \( m' = m + C[.., j] \) (\( C[.., j] \) is the \( j \)th column
of \( C \)) and this is denoted by \( m \rightarrow_{t_j} m' \). The set of all the markings reachable
from \( m_0 \) is called reachability set, and is denoted by \( \text{RS}(m_0) \).

Semiflows are non-null natural annihilers of \( C \). Right and left annihilers are called
T- and P-(semi)flows respectively. A semiflow is called minimal when its support
(i.e., the set \( \|s\| \) of the non-zero components of vector \( s \)) is not a proper superset
of the support of any other, and the g.c.d. of its elements is one.
2.2 Previous Product Form solution results for stochastic Petri nets

A class of SPNs characterized by the fact that the stationary probability distribution of any net in this class can be factored into a product of terms has been introduced [11, 13]. Nets possessing this property are called Product-Form Stochastic Petri Nets (PF-SPNs) and are easily identified by the criteria proposed in [2, 7, 11, 13].

Let $x_1, x_2, \ldots, x_h$ denote the minimal T-semiflows found from the incidence matrix. The following definitions are essential to the analysis of the SPNs that have Product Form Solution.

**Definition 1.** A subset of transitions $T'$ ($T' \subseteq T$) is said to be closed if $\bigcup_{t_j \in T'} i(t_j) = \bigcup_{t_j \in T'} o(t_j)$. An alternative definition of a closed set of transitions is the following: let $R(T') = \bigcup_{t_j \in T'} \{i(t_j) \cup o(t_j)\}$ be the set of input and output bags for transitions in $T'$. The subset of transitions $T'$ is said to be closed if for any $1 \in R(T')$ there exists $t_i, t_j \in T'$ such that $1 = i(t_i)$ and $1 = o(t_j)$; that is, each output bag is also an input bag for some transition in $T'$, and vice-versa each input bag is also an output bag.

**Definition 2.** $\mathcal{N}$ is a II-net if $\forall t_j \in T$ there exists a minimal T-semiflow $x$ such that $t_j \in \|x\|$, and $\|x\|$ is a closed set.

In other words, $\mathcal{N}$ is a II-net if all transitions are covered by closed support minimal T-semiflows.

*Example of II-net* Figure 1(a) shows a net satisfying Definition 2. We can see that there are two minimal T-semiflows $x_1 = [1, 0, 1, 0]$ and $x_2 = [0, 1, 0, 1]$, with $\|x_1\| = \{t_1, t_3\}$ and $\|x_2\| = \{t_2, t_4\}$. We can observe that

$$\{[1, 0, 0, 0], [0, 0, 1, 0]\} = \bigcup_{t_j \in \|x_1\|} o(t_j) \quad \text{and} \quad \bigcup_{t_j \in \|x_2\|} i(t_j) = \{[1, 1, 0, 0], [0, 0, 0, 1]\}$$

Both T-semiflows have closed support set. Since any transition belongs to a closed support minimal T-semiflow, this net is a II-net.

The definition of II-nets was originally motivated while studying the problem of finding product form solution for SPNs [2, 7, 11, 13]. More precisely, for the SPNs having the II property, there exists a positive solution for the traffic equations (see below). In a II-net we denote by $\mathcal{X}_c = \{x_1, x_2, \ldots, x_h\}$ the set of closed support minimal T-semiflows. Among the minimal closed support T-semiflows, we can identify a relation that can be used to derive the PFS. Two different minimal closed support T-semiflows $x'$ and $x''$ are said to be freely related, denoted as $(x', x'') \in FR$, if there exist $t_j \in \|x'\|$ and $t_h \in \|x''\|$ such that $i(t_j) = i(t_h)$. The relation $FR^*$ is the transitive closure of FR. It is easy to see that the relation $FR^*$ yields a partitioning of the set of minimal closed support T-semiflows. Because any $t_j$ can belong to only one FR-class, the partition of T-semiflows leads to a partition of transitions. In the following we denote by $C(t_j)$ the set of the partition to which transition $t$ belongs.
As for Queueing Networks, PF solutions for SPN are based on the analysis of underlying Markov chains (MC). Instead of reasoning in terms of the MC with states as markings, it is more convenient to study an auxiliary MC with states being the input (or output) vectors \( \mathbf{i}(t) \), called the routing process \[11\] of the SPN. The infinitesimal generator \( \mathcal{Q} \) of this MC is defined by:

\[
g(\mathbf{i}(t_j), \mathbf{o}(t_j)) = \mu(\mathbf{i}(t_j))\mathbf{P}[\mathbf{i}(t_j), \mathbf{o}(t_j)] \quad \text{with} \quad \mu(\mathbf{i}(t_j)) = \sum_{\mathbf{h}(t_h) = \mathbf{i}(t_j)} \mu_h.
\]

\( \mathbf{P}[a, b] \) is the routing probability from \( a = \mathbf{i}(t_j) \) to \( b \); it can be computed by examining the various transitions enabled after the firing of \( t_j \) and \( \mu_h \) is the usual rate of SPN transition \( t_h \). For the sake of simplicity, we present all the results by assuming that the transition rates are marking independent. In \[10\] results are presented with several kinds of marking dependent transition firing rates.

The traffic equations of the routing process are the global balance equations of this MC. Denoting with \( v(\mathbf{i}(t_j)) \) the so-called visit-ratio to node \( \mathbf{i}(t_j) \), these equations can be stated as:

\[
\forall t_j \in \mathcal{T}, \quad v(\mathbf{i}(t_j)) = \sum_{t_h \in \mathcal{T}} v(\mathbf{i}(t_h))\mathbf{P}[\mathbf{i}(t_h), \mathbf{i}(t_j)]
\]

Boucherie and Sereno \[2\] showed that traffic equations and structural properties of a net are closely related.

**Theorem 1 (from \[2\]).** Let \( \mathcal{N} = (\mathcal{P}, \mathcal{T}, W, \mathcal{Q}, \mathbf{m}_0) \) be a SPN. There is a non null positive solution for the Traffic Equations (1) iff \( \mathcal{N} \) is a II-net.

The existence of a positive solution for the Traffic Equations (1) is not a sufficient condition to assert a Product-Form Solution for the SPN. The following result from Coleman *et al.* \[7\] and \[11\], states that the equilibrium distribution has a product-form over the places of the SPN whenever one additional condition holds. Let \( \mathbf{f} = \mathbf{v}/\mu \) with \( \mathbf{v} \) a solution for the traffic equations, and define the vector \( \mathbf{w}_f = [w_1, \ldots, w_n] \) as

\[
\mathbf{w}_f = \left[ \log \left( \frac{f(\mathbf{i}(t_1))}{f(\mathbf{o}(t_1))} \right), \log \left( \frac{f(\mathbf{i}(t_2))}{f(\mathbf{o}(t_2))} \right), \cdots, \log \left( \frac{f(\mathbf{i}(t_m))}{f(\mathbf{o}(t_m))} \right) \right]
\]
There may be many functions \( f \) that derive from solutions for the traffic equations. However each one is unique up to a multiplicative constant in each FR* class. This implies that the ratio \( f(i(t_i))/f(o(t_i)) \) is invariant.

**Theorem 2 (Product-Form for Equilibrium Distribution of SPN, (from [7, 11])).** Let \( f = v/\mu \) with \( v \) a solution for the traffic equations. The equilibrium distribution for the SPN has the form

\[
\pi(m) = \frac{1}{G} \prod_{i=1}^{np} g_i^{m_i} \quad \forall \; m \in RS(m_0)
\]

if and only if \( \text{Rank}(C) = \text{Rank}([C \mid w_f]) \) where \([C \mid w_f] \) is the matrix \( C \) augmented with the row \( w_f \) and \( G \) a normalization constant. In this case, the \( np \)-component vector \( r = [\log(y_1), \ldots, \log(y_{np})] \), satisfies the matrix equation

\[-r.C = w_f.\]

It must be noted that, generally, the condition \( \text{Rank}(C) = \text{Rank}([C \mid w_f]) \) depends on the rates of the transitions of the net and not only on the structure of the net.

### 2.3 Examples of II-nets

Let us present two detailed examples of II-nets. The first one complements the study of the net of Figure 1(a) and the second one shows a more complex situation about the rank condition of Theorem 2. The reader will also find an example of an unbounded II-net in Section 4.3.

**Example 1** In this example we briefly review the procedure used to obtain the equilibrium distribution for the \( II \)-net depicted in Figure 1(a). For additional details the reader is referred to [2, 7, 11–13]. Since we know that the SPN is a \( II \)-net, there is a solution for the Traffic equations (1):

\[
v(i(t_1)) = v(i(t_3)) \quad v(i(t_1)) = v(i(t_4))
\]

\[
v(i(t_2)) = v(i(t_3)) \quad v(i(t_2)) = v(i(t_4)) = 1
\]

One solution is \( v(i(t_1)) = v(i(t_3)) = v(i(t_2)) = v(i(t_4)) = 1 \), from which we obtain \( f(i(t_1)) = 1/\mu_1, f(i(t_3)) = 1/\mu_3, f(i(t_2)) = 1/\mu_2 \), and \( f(i(t_4)) = 1/\mu_4 \). The row vector \( w_f \) is:

\[
w_f = [\log(f(i(t_1))/f(i(t_3))), \log(f(i(t_2))/f(i(t_4))), \log(f(i(t_3))/f(i(t_1))), \log(f(i(t_4))/f(i(t_2)))] = [\log(\mu_3/\mu_1), \log(\mu_4/\mu_2), \log(\mu_1/\mu_3), \log(\mu_2/\mu_4)]
\]

The rank condition \( \text{Rank}(C) = \text{Rank}([C \mid w_f]) \) gives us:

\[
\begin{pmatrix}
-1 & 1 & 1 \\
0 & -1 & 0 \\
1 & 0 & -1 \\
0 & 1 & 0
\end{pmatrix} = \text{Rank} \begin{pmatrix}
-1 & -1 & 1 & 1 \\
0 & 1 & 0 & 1 \\
1 & 0 & -1 & 0 \\
0 & 1 & 0 & -1
\end{pmatrix}
\]

\[
w_1 \; w_2 \; w_3 \; w_4
\]
The rank condition holds independently of the rate values because we can easily verify that \( w_1 + w_3 = 0 \) and \( w_2 + w_4 = 0 \) since \( \log \left( \frac{a_1}{\mu_1} \right) + \log \left( \frac{a_1}{\mu_3} \right) = \log \left( \frac{a_1 a_1}{\mu_1 \mu_3} \right) = \log(1) = 0 \) and similarly for \( w_2 + w_4 = 0 \).

Since theorem 2 applies, we can obtain the expression of \( \pi(m) \). To this end, we first solve the matrix equation \( r.C + w_f = 0 \), that is to say:

\[
  -r_1 + r_3 + w_1 = 0 \\
  -r_1 - r_3 + w_3 = 0 \\
  -r_1 - r_2 + r_4 + w_2 = 0 \\
  r_1 + r_2 - r_4 + w_4 = 0.
\]

Then, setting \( r_1 = r_2 = 0 \), we obtain \( r_3 = w_3 \) and \( r_4 = w_4 \) from which we derive \( (r_i = \log(y_i)), y_1 = y_2 = 1, y_3 = \mu_1/\mu_3, \) and \( y_4 = \mu_2/\mu_4 \). Hence the equilibrium distribution of the SPN of Figure 1(a) is \( \pi(m) = \frac{1}{C} \left( \frac{\mu_1}{\mu_3} \right)^{m_3} \left( \frac{\mu_2}{\mu_4} \right)^{m_4} \).

**Example 2** The SPN shown in Figure 1(b), taken form [7], represents an SPN in which the rank condition is not satisfied independently of the rate values. The incidence matrix \( C \) is given by \( C = \begin{pmatrix} -1 & 2 & -2 & 1 \\ 1 & -2 & 2 & -1 \end{pmatrix} \). This SPN is covered by four minimal T-semiflows whose support sets are \( ||x_1|| = \{t_1, t_4\}, ||x_2|| = \{t_2, t_3\}, ||x_3|| = \{2t_1, t_2\}, \) and \( ||x_4|| = \{t_3, 2t_4\} \). Only \( x_1 \) and \( x_2 \) are closed, but they cover \( T \) so that the SPN satisfies Definition 2. Then the SPN is a \( H \)-net and hence there exists a positive solution for the traffic equations. In particular we obtain \( f(t_i(t)) = \frac{1}{\mu_i} \) for \( i = 1, \ldots, 4 \). The vector \( w_f \) is given by

\[
  w_f = \begin{bmatrix} 
  \log \left( \frac{f(t_1(t))}{f(t_3(t))} \right) \\
  \log \left( \frac{f(t_2(t))}{f(t_3(t))} \right) \\
  \log \left( \frac{f(t_1(t))}{f(t_2(t))} \right) \\
  \log \left( \frac{f(t_1(t))}{f(t_4(t))} \right) \\
  \log \left( \frac{f(t_1(t))}{f(t_4(t))} \right) \\
  \log \left( \frac{f(t_2(t))}{f(t_4(t))} \right)
  \end{bmatrix}
\]

The augmented matrix \( [C \mid w_f] \) is row equivalent to the fully row reduced matrix \( \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \). The rank conditions are \( w_2 + 2w_1 = 0 \), \( w_3 - 2w_1 = 0 \), and \( w_1 + w_4 = 0 \), which implies \( \frac{f(t_1(t))}{f(t_3(t))} = \left( \frac{f(t_1(t))}{f(t_2(t))} \right)^2 = 1 \), and \( 1 = 1 \) respectively. The first and second conditions are the same and arise because there is more than one way to produce the same change of marking. Substituting for the function \( f \), the rank condition becomes \( \frac{\mu_1}{\mu_3} = \left( \frac{\mu_2}{\mu_4} \right)^2 \). If this condition is met, theorem 2 applies, and, letting \( y_2 = 1 \) gives \( y_1 = \frac{f(t_1(t))}{f(t_3(t))} \). Finally, \( \pi_f(m) = \left( \frac{\mu_3}{\mu_1} \right)^m \).
3 The class of $II$-nets

In this section we are interested in structural properties of $II$-nets. We present first an important result which allows one to check, in polynomial time\(^1\), whether a given SPN is or not a $II$-net. Then, trying to position the class of $II$-nets with respect to classical structural classes of PN, we show that there is no simple relation between these classes and $II$-nets.

3.1 Membership problem

Algorithm Verify $II$-net
\[
L ← T
\]
fail ← false
repeat
let \( t \in L \)
\( A ← \{ t \} \)
\( In ← \{ i(t) \} \)
\( Out ← \{ o(t) \} \)
while \( \exists t' \in L \) s.t. \( i(t') \in Out \) do
\( A ← A ∪ \{ t' \} \)
\( L ← L \setminus \{ t' \} \)
\( In ← In \cup \{ i(t') \} \)
\( Out ← Out \cup \{ o(t') \} \)
endwhile
fail ← (In ≠ Out) /* if not fail then A is a FR* class */
until \( L = \emptyset \) or fail
/* fail is true iff the net is not a $II$-net */

From the definition of $II$-nets we can decide if a given net falls in this class. The problem that arises is the complexity of a straightforward application of Definition 2 because the number of minimal T-semiflows can be exponential in the number of transitions (e.g., [17]). We present now an algorithm that allows to recognize whether a net is a $II$-net in polynomial time. The soundness of the algorithm is based on the following lemma (see [2] for the proof).

**Lemma 1.** If \( x \) is a closed support minimal T-semiflow then (i) for each transition \( t_i \in ||x||, x[i] = 1 \) (\( x[i] \) is the \( i \)-th component of \( x \)), (ii) \( ||x|| \) may be ordered as \( \{ t_{j_0}, t_{j_1}, \ldots, t_{j_{h−1}} \} \) such that \( o(t_{j_i}) = i(t_{j_{i+1 \mod h}}) \) (for \( i = 0, 1, \ldots, h − 1 \)), and \( l ≠ l' → i(t_{j_l}) ≠ i(t_{j_{l'}}) \).

**Algorithm for $II$-net membership** The previous lemma states that a closed support minimal T-semiflow can be seen as a cycle of transitions \( t_{j_0}, t_{j_1}, \ldots, t_{j_{h−1}} \) such that \( o(t_{j_i}) = i(t_{j_{i+1 \mod h}}) \) (for \( i = 0, 1, \ldots, h − 1 \)). The algorithm **Verify $II$-net** exploits this feature for checking if a net is a $II$-net.

---

\(^1\) Unless explicitly mentioned, all complexity results in the paper are w.r.t. the size of the net, i.e. the number of places, transitions, arcs and the binary representation of valuations.
We point out that the algorithm yields a covering set of closed support minimal T-semiflows (if the SPN is a II-net). From then we can derive the routing probabilities and the partitions of the set of transitions $T$ into $FR^*$-classes.

From simple considerations we can see that both the inner and the outer cycles require $O(|T|)$ steps. Hence the complexity of the algorithm that allows to recognize if a given net satisfy Definition 2 requires $O(|T|^3)$ steps.

### 3.2 II-nets and other classes of PN

As usual for Petri net models, it is interesting to examine whether it is possible to structurally characterize behavioural properties of these nets and to deduce efficient checking of these properties. Since this is the case for some well known subclasses of nets, we first recall such subclasses and we compare II-nets with them. For completeness, results include the class of $\overline{II}$-nets which are introduced in section 3.3.

\[ (a) \quad \text{II-net} \quad \Rightarrow \quad (b) \quad \text{MG} \]

**Fig. 2.** Conversion of WTS II-nets into MGs

The following classes of Petri nets are particularly interesting for the analysis of behavioural properties:

- A state machine (SM) is a Petri net with binary valuations where any transition has exactly one input and one output place.
- A marked graph (MG) is a Petri net with binary valuations where any place has exactly one input and one output transition.
- A weighted transition system (WTS) is a Petri net where any place has exactly one input and one output transition (MG are special case of WTS).
- An extended free-choice net (EFC) is a Petri net with binary valuations where two transitions, sharing an input place, have the same set of input places.

**Proposition 1.** Comparing II-nets with some classical subclasses of Petri nets, we have:

- If $\mathcal{N}$ is a WTS and a II-net, then it is behaviorally equivalent to a MG.
Every SM is a $\Pi$-net (and even a $\overline{\Pi}$-net).

There are MGs which are not $\Pi$-nets.

There are $\Pi$-nets (and even $\overline{\Pi}$-nets) which are non EFC nets.

Proof. Figure 2 explains the conversion from a WTS $\Pi$-net to a MG: in (a) we change the weights of arcs connecting isolated places ($k = w_1 - w_2$); in (b), we observe that any weighted $\Pi$-cycle is just equivalent to an ordinary cycle.

As a straightforward consequence of the definitions, every SM is a $\Pi$-net. In any SM, r vectors are $1_p$: null components except on component $p$, input or output place of a transition $t$. Taking $a_r = r$ for each $r$, we see that a SM is also a $\Pi$-net (see below for definition of $\overline{\Pi}$-nets).

A net with an idle place followed by a parbegin-parend with intermediate action is a MG but not a $\Pi$-net. Note however, that any $\Pi$-net MG is a union of disjoint cycles, hence a $\overline{\Pi}$-net.

Finally, we will see that the net of Example 1 (Figure 1(a)) is a $\overline{\Pi}$-net, and it is clearly not an EFC.

3.3 $\overline{\Pi}$-nets

In this section we define the class of $\overline{\Pi}$-nets which are exactly the set of $\Pi$-nets having a PF solution for any stochastic specification in contrast with previous results whose criteria are dependent on rates of transitions (see Example 2).

Moreover, we introduce a more general dependency of the firing rates of transitions with respect to the global marking of the net system.

Definition of $\overline{\Pi}$-nets Criteria found by several authors since the late 80’s for PF solution of SPN are only sufficient conditions, and moreover, they are made up of structural conditions and conditions on the stochastic parameters of the SPN. In search of a pure structural characterization of PF solution SPN, we were led to fully reconsider the concept of "virtual client state" of a $\Pi$-net system in the context of routing processes and to deeply analyze how to characterize these states. In previous works, T-semiflows identify concurrent "virtual clients" activities. These activities are synchronized by conflicting resources allocation, that is shared input places of transitions. For what concerns places, they are usually interpreted either as specific resources or as clients. But, indeed, this interpretation does not allows us to express the PF property at a structural level because virtual client states do not reduce to place markings, even in a $\Pi$-net. For instance, in the example net 1 (figure 1(a)), we may think of $t_1, p_3, t_3$ as batch jobs processing (activity 1), and of $t_2, p_4, t_4, p_2$ as interactive work of users (activity 2). The place $p_1$, modelling processor resources, cannot, alone, characterize the "idle" batch jobs state. This is the crucial point: in a $\Pi$-net, we have no information about the state of the virtual clients in the net system and this is the main reason which prevents us to state a necessary and sufficient condition for the existence of a PF solution. Actually, we have found that virtual client states are characterized by a relation $v.C = r$, where $v$ is a vector on places and $r$ is a vector such that $r[t] = 1$ if $t$ adds a client to the "state", $r[t] = -1$ if $t$
removes a client and $r[t] = 0$ otherwise. The $\overline{I}$-net property expresses, by means of rational vectors $a_r$, the relation which must hold between virtual clients states of a $I$-net and input/output vectors of the net, to ensure that this $I$-net has a PF solution.

Moreover, this explicit relation on states of virtual clients allows us to model the dependency of the firing rate of a transition $t_j$ with respect to the global state of the system in parts (activities) of the net not related to the input/output vectors of transitions belonging to $C(t_j)$. This kind of dependency, introduced by functions $\rho_{C(t_j)}$ in the definition below, cannot be taken into account in the framework of $I$-nets.

For the rest of this section, we set: $r^* = \{ t_j \in T \mid o(t_j) = r \}$ and $r^\bullet = \{ t_j \in T \mid i(t_j) = r \}$ for every $r \in \mathcal{R}(T)$.

**Definition 3 ($\overline{I}$-net).** A $\overline{I}$-net (restricted $I$-net) is a $I$-net such that for every $r \in \mathcal{R}(T)$, there exists $a_r \in \mathbb{Q}^{|\mathcal{R}|}$ such that

$$a_r.C[p, j] = \begin{cases} 1 & \text{if } t_j \in r^\bullet \\ -1 & \text{if } t_j \in r^* \\ 0 & \text{otherwise} \end{cases}$$

where $C$ is the incidence matrix of the net (note that this excludes transitions $t_h$ with $i(t_h) = o(t_h)$).

The firing rate of a transition $t_j$ of a $\overline{I}$-net system in the marking $m$ is given by

$$\mu(t_j, m) = \mu(i(t_j)) \cdot \rho_{C(t_j)}((a_{r^\bullet} \cdot m)_{r^\bullet \in C(t_j)}) \cdot P[i(t_j), o(t_j)]$$

(4)

Positive, real valued functions $\rho_{C(t_j)}((a_{r^\bullet} \cdot m)_{r^\bullet \in C(t_j)})$ make possible a homogeneous dependency of the transitions of the component $C(t_j)$ w.r.t. the state of the virtual clients in the other components, given by the $a_{r^\bullet} \cdot m$ (see example below).

Note that the computation of the rational vectors $a_r$ (or else the proof that there are no such $a_r$), may be achieved in polynomial time with respect to the size of the net through a usual Gaussian elimination (but restricted to rational numbers).

The net of Example 2 is an example of a $\overline{I}$-net which is not a $I$-net (see its incidence matrix in Section 2.3). Let us set $r_1 = \{ p_1 \}$, so that $r^\bullet_1 = \{ t_4 \}$ and $r^\bullet_1 = \{ t_1 \}$. If we try to define the vector $a_{r_1} = [a, b]$, we get $a - b = 1$ (since $t_4 \notin r^\bullet_1$ and $a - b = 0$ (since $t_2 \notin r^\bullet_1 \cup r^\bullet_1$). Hence, $a_{r_1}$ does not exist and this SPN is not a $\overline{I}$-net. In fact, $t_1$ and $t_3$ have proportional input and output bags but belong to different T-semiflows and no distinction between these transitions is possible from $t_1 = [1, 0, 0, 0, 0, 0]$, $t_4 = [0, 0, 0, 0, 1]$.

The $I$-net of Example 1 (see Section 2.3) is a $\overline{I}$-net. We have four input vectors $r$, belonging to two classes: $C_1 = \{ r_1 = [1, 0, 0, 0], r_3 = [0, 0, 1, 0] \}$, $C_2 = \{ r_2 = [1, 1, 0, 0], r_4 = [0, 0, 0, 1] \}$. The $a_r$ vectors are

$a_{r_1} = [0, 0, -1, 0] \quad a_{r_3} = [0, 0, 1, 0]$

$a_{r_2} = [0, 0, 0, -1] \quad a_{r_4} = [0, 0, 0, 1]$
Let us assume that the rate of \( t_3 \) depends on the load of \( t_4 \) in such a way that if the marking of \( p_4 \) is greater than \( K_4 \), \( t_3 \) cannot fire (because no more resource is available for instance). Moreover, suppose that the rate of \( t_4 \) decreases linearly from \( \mu_M \) to \( \mu_m \) with the marking of \( p_4 \) varying from 0 to \( K_4 \). Then we can define

\[
\rho_C(t_3) \left((a_{r'}, m)\right)_{r' \not\in C(t)} = \begin{cases} 0 & \text{if } m[p_4] \geq K_4 \\ \frac{\mu_m - \mu_M}{K_4} m[p_4] + \mu_M & \text{if } 0 \leq m[p_4] < K_4 \end{cases}
\]

since \( a_{r_4} m = m[p_4] \) and we have still a PF steady state distribution.

Due to lack of space, we present in the rest of the paper, results without functions \( \rho_C(t) \). The reader will find full version of the results in the technical report [10].

**Sufficient condition for PF-SPN** We first establish a sufficient condition for a \( \Pi \)-net to have a PF steady state distribution, *whatever* the parameters (i.e. rates of transitions) of the stochastic specification of the SPN.

**Theorem 3.** Let \((P, T, W, Q, m_0)\) be a \( \Pi \)-net. Then, for any transition rates, the steady state distribution of the SPN has the product form

\[
\pi(m) = \frac{1}{G} \prod_{r \in R(T)} \left( \frac{v(r)}{\mu(r)} \right)^{a_r m}, \quad \forall m \in RS(m_0),
\]

where \( G \) is a normalization constant and \( v \) is a solution of Equations (1).

Let us remark that this product form expression induces, of course, a product form with respect to \( m \) since:

\[
\prod_{r \in R(T)} \left( \frac{v(r)}{\mu(r)} \right)^{a_r m} = \prod_{r \in R(T)} \prod_{i \in P} \left( \frac{v(r)}{\mu(r)} \right)^{a_r[i] m[i]} = \prod_{r \in R(T)} \left( \prod_{i \in P} \left( \frac{v(r)}{\mu(r)} \right)^{a_r[i]} \right)^{m[i]}
\]

**Sketch of proof** We give only a sketch of the proof (see [10] for a detailed proof). The starting point is the so-called the Group Local Balance Equation for a marking \( m \) with respect to a given vector \( r \) which is a splitting of the equilibrium (Chapman-Kolmogorov) equations of the Markov chain with markings as states:

\[
\pi(m) \sum_{t_j \in \mathcal{E}^*} q(m, m - i(t_j) + o(t_j)) = \sum_{t_h \in \mathcal{E}^*} \pi(m + i(t_h) - o(t_h))q(m + i(t_h) - o(t_h), m)
\]

Then using the expression of the rates \( q \), we introduce the proposed expression and after simplification, we get:

\[
\mu(r) = \sum_{t_h \in \mathcal{E}^*} \prod_{r' \in R(T)} \left( \frac{v(r')}{\mu(r')} \right)^{a_r'(i(t'_h) - o(t_h))} \mu(i(t_h))P[i(t_h), r].
\]

From \( i(t_h) - o(t_h) = -C[P, h] \) and the definition of \( a_r \), (7) can be shown equivalent to the Traffic Equations (1).
Necessary condition for PF-SPN The result of this section proves that the concept of $\Pi$-net is the adapted one to capture the existence of a product form like the one of Theorem 3 for any stochastic specification of a $\Pi$-net. Combining Theorems 3 and 4, the "$\Pi$-net property" appears as a necessary and sufficient structural condition for a net to have a product form steady state distribution for any transition rates.

**Theorem 4.** Let $(P, T, W, Q, m_0)$ be a $\Pi$-net and $v$ a solution of the Traffic Equations. If there is a family $(a_r)_{r \in R(T)}$ of rational vectors such that the distribution

$$\pi(m) = \frac{1}{G} \prod_{r \in R(T)} \left( \frac{v(r)}{\mu(r)} \right)^{a_r \cdot m} \quad \forall m \in RS(m_0),$$

satisfies the Group Local Balance Equations (6) for any $(\mu(r))_{r \in R(T)}$, then we have

$$a_r \cdot C[P, j] = \begin{cases} 1 & \text{if } t_j \in \bullet r, \\ -1 & \text{if } t_j \in \circ r, \\ 0 & \text{otherwise} \end{cases}$$

**Sketch of proof** (see [10] for a detailed proof). The Group Local Balance Equations for a given $m$ with respect to a given $r$ are (see (7))

$$\mu(r) = \sum_{t_j \in \bullet r} \prod_{r' \in R(T)} \left[ \frac{v(r')}{\mu(r')} \right] ^{-a_r \cdot C[P, j]} = a_r \cdot C[P, j] \mu(i(t_j))P[i(t_j), r]$$

(8)

since $a_r \cdot C[P, j] = -a_r \cdot C[P, j].$

The idea is to express (8) as a multi-variables identically null "polynomial" (i.e. extension of multi-variables polynomial, with real valued exponents instead of integer) on $\mathbb{R}^+$ and to deduce the claimed properties of the $r$ vectors from properties of the coefficients of this "polynomial". To this end, we introduce the vectors with $np$ components $\gamma(t_j)$ and $\gamma_0$ in the following way:

$$\gamma(t_j)[r'] = \begin{cases} a_{r'} \cdot C[P, j] & \text{if } r' \neq i(t_j) \\ a_{r'} \cdot C[P, j] + 1 & \text{if } r' = i(t_j) \end{cases} \quad \text{and} \quad \gamma_0[r'] = \begin{cases} 1 & \text{if } r' = r \\ 0 & \text{otherwise} \end{cases}$$

Using these vectors, transformation of Equation (8) provides a "polynomial" with variables $\mu(r')$. Via a technical result, it can then be shown that for all $t_j$, the set $\{r_j \in \circ r \mid \gamma(t_j) = \gamma_0\}$ is empty, so that $\forall t_j \in \bullet r$, $\gamma(t_j) = \gamma_0$. The result then follows from the evaluation of the numbers $a_{r'} \cdot C[P, j].$

4 Functional properties of PF-SPN

Although $\Pi$-nets and $\Pi$-nets are not easily comparable to standard classes of PN, they nevertheless enjoy specific qualitative properties. This section first reviews liveness and deadlock freeness in $\Pi$-nets; second, some results about the
complexity of the reachability and liveness in $\Pi$-nets and $\Pi$-nets are presented. Finally, we expose results about the characterization of reachable markings in $\Pi$-nets. Since we need to distinguish between structural and behavioural properties of (S)PN, in this section, we denote by $\mathcal{N} = (\mathcal{P}, \mathcal{T}, W, Q)$ a SPN and by $\Sigma = (\mathcal{N}, \mathbf{m}_0)$ a marked SPN (also called SPN system) with initial marking $\mathbf{m}_0$.

4.1 Some behavioural properties of $\Pi$-nets

Liveness is an important property of Petri net systems. Due to importance of T-semiflows in $\Pi$-nets, it is not surprising that liveness in $\Pi$-nets systems enjoys particular properties that we present below together with related results. The following lemma is a direct consequence of Proposition 1.

**Lemma 2.** Let $\Sigma = (\mathcal{N}, \mathbf{m}_0)$ be a $\Pi$-system. If $t \in \mathcal{T}$ is enabled at $\mathbf{m} \in \text{RS}(\mathbf{m}_0)$, then,

1. all transitions of all minimal closed support T-semiflows to which $t$ belongs can be fired,
2. there is a firing sequence that fires all the remaining transitions in the FR*-class of $t$.

**Proposition 2.** Let $\Sigma = (\mathcal{N}, \mathbf{m}_0)$ be a $\Pi$-system.

1. If $\exists t \in \mathcal{T}$, enabled at $\mathbf{m}_0$ then $\Sigma$ is deadlock-free (DF).
2. $\Sigma$ is reversible.
3. $\mathcal{N}$ is structurally live (SL).
4. If there is an enabled transition in any FR*-class in the initial marking then $\Sigma$ is live. The converse is false.
5. If $\Sigma$ is live then $\Sigma' = (\mathcal{N}, \mathbf{m}_0')$ with $\mathbf{m}_0 \leq \mathbf{m}_0'$ is live too (i.e., liveness is monotonic w.r.t. the initial marking in the net).

**Proof.** We only give the detailed proof of (2).

If $\mathbf{m}_0$ is not a deadlock marking, for any $\mathbf{m} \in \text{RS}(\mathbf{m}_0)$ there is a finite firing sequence $\sigma = t_{s_1}, t_{s_2}, \ldots, t_{s_k}$ such that $\mathbf{m}_0[t_{s_k} \ldots m_{i-1}[s_k] \mathbf{m}$. Now we prove that there is a finite firing sequence $\eta$ such that $\mathbf{m}[\eta] \mathbf{m}_0$. Let $x$ be a closed support T-semiflow (not necessarily minimal) such that $x \geq \sigma$. Since $x$ is a linear combination of minimal closed support T-semiflows, it follows from Lemma 2 that from $\mathbf{m}$, $x - \sigma$ must be free and hence $\mathbf{m}[x - \sigma] \mathbf{m}_0$.

**Reverse of $\Pi$-net** Finally, the next proposition addresses properties of the reverse net of $\Pi$-nets. The reverse net of a Petri net $\mathcal{N} = (\mathcal{P}, \mathcal{T}, W)$ is $\mathcal{N}^{-1} = (\mathcal{P}, \mathcal{T}, W^{-1})$, that is, the net with same places and transitions, but reversed arcs ($W^{-1}(i,j) = W(j,i)$). Note that $(\mathcal{N}^{-1})^{-1} = \mathcal{N}$ and that the incidence matrix of $\mathcal{N}^{-1}$ is $-C$.

**Proposition 3.** Let $\mathcal{N}$ be a $\Pi$-net, $\Sigma = (\mathcal{N}, \mathbf{m}_0)$, and $\Sigma^{-1} = (\mathcal{N}^{-1}, \mathbf{m}_0)$.

1. The reverse of a $\Pi$-net (resp. $\Pi$-net) is a $\Pi$-net (resp. $\Pi$-net).
2. $\Sigma$ is deadlock free iff $\Sigma^{-1}$ is deadlock free.
3. The reachability graph of $\Sigma^{-1}$ is the reverse of the reachability graph of $\Sigma$. 

4. \( \Sigma \) is live iff \( \Sigma^{(-1)} \) is live.

Proof. For space savings, we only develop proof of (3). If \( m_0 \) is not a deadlock marking then from Proposition 2 (1) and (2), \( \Sigma \) is reversible. But in any reversible Petri net, the announced property holds. Indeed, we have first \( \text{RS}(\Sigma^{(-1)}) = \text{RS}(\Sigma) \). Let \( m \in \text{RS}(\Sigma) \). Since \( \Sigma \) is reversible, there is a firing sequence \( \tau \) such that \( m[\tau]m_0 \). Therefore, \( m_0[\tau^{(-1)}]m \) in \( \Sigma^{(-1)} \) where \( \tau^{(-1)} \) is \( \tau \) with "reversed" transitions. Now, let \( m[l]m' \) in \( \Sigma \). We have \( m' \in \text{RS}(\Sigma^{(-1)}) \) and, obviously, \( m'[l^{(-1)}]m \). We have proven that the reverse of the reachability graph \( \Sigma \) is a partial graph of \( \Sigma^{(-1)} \). The result follows, applying the same proof to \( \Sigma^{(-1)} \).

4.2 Complexity of liveness and reachability problems for \( \Pi \)-nets and \( \overline{\Pi} \)-nets

![Diagram of 3SAT reduction to liveness in 1-safe \( \overline{\Pi} \)-nets](image)

Fig. 3. Reduction of 3SAT to liveness in 1-safe \( \overline{\Pi} \)-nets

---

Condition (4) in proposition 2 is only a sufficient condition. In fact, checking liveness seems no more easy for \( \Pi \)-nets, and even 1-safe\(^2\) \( \overline{\Pi} \)-nets, than for many

---

\(^2\) A 1-safe marked Petri net is a (bounded) marked net with at most one token in every place of every reachable marking
other classes of Petri nets. We have shown in Section 3.1 that the complexity of the computation of FR*-Classes is polynomial time. But checking liveness requires to verify that each FR*-class is live. If some FR*-class is not initially
firable, this is still a very complex problem. Indeed the next lemma gives some
insight into this point. We recall that for general Petri nets, Lipton’s result [16]
implies a $2^{O(\sqrt{n})}$ lower bound space complexity for the liveness problem
(see [9, 8] for recent surveys on decidability problems for Petri nets). In fact,
we are able to give more precise results, although the exact complexity of the
readability/liveness for $\Pi$-nets still remains an open problem.

It has been shown in [6] that the liveness problem for 1-safe nets is PSPACE
complete. The next lemma gives a lower bound of the problem for 1-safe $\Pi$-nets.

**Proposition 4.** The liveness problem for 1-safe $\Pi$-nets is NP-hard.

**Proof.** To prove it, we reduce in polynomial time the 3SAT problem to the
liveness problem for $\Pi$-nets, following the idea first presented in [14]. The 3SAT
problem is a well known NP-complete problem. We have $K$ logical formulae
$C_1, \ldots, C_K$, each one being a disjunction of three boolean variables $v_i$ or their
negation ($\neg v_i$), from a set of $I$ variables; for instance, $C_k = v_1 \vee \neg v_3 \vee v_6$. The
3SAT problem is: is there a set of values for $v_1, \ldots, v_I$ such that $C_1 \land C_2 \land \ldots \land C_K$
is true? We explain the reduction through the example $C_1 = v_1 \land \neg v_2 \land v_3,$
$C_2 = v_2 \land v_3 \land v_4$ ($K = 2, I = 4$) (Figure 3).

For each variable $v_i$, we have two places $p_i$ and $p_{\neg i}$ and two transitions $t_i$
and $t_{\neg i}$, Arcs between places and transitions for $v_i$ are as indicated in the figure.
We have also $K$ sets of places $p_{C_1}, \ldots, p_{C_K}$ (the introduction of several places for each
C formulae ensures 1-safeness). If $v_i$ is in $C_k$ (like $v_2$ and $C_2$) there is an arc
from $t_{\neg i}$ to $p_{C_k}$, and one arc from $p_{C_k}$ to $t_i$. In contrast if $v_i$ is in $C_k$ (like
$\neg v_2$ in $C_1$), these arcs are reversed. Otherwise, there is no arc between $t_i$, $t_{\neg i}$
and place $p_{C_k}$. Places detailed in the right dotted part ensure that the place
$p_{C_k}$ will contain at most one token ($p_{C_2}$s is a mutex place). Finally, we have one
transition $t_{s_1}$ (for Success) and we added place $p_s$ and transition $t_{s_2}$ to have a
$\Pi$-net and not only a $\Pi$-net.

We can easily verify that the net is a 1-safe $\Pi$-net. The initial marking
is chosen as follows: if $v_i$ is true, there is one token in $p_i$ and one token in place $p_{C_k}$
if $v_i$ is in $C_k$; if $v_i$ is false, there is one token in $p_{\neg i}$ and one token in place $p_{C_k}$
if $\neg v_i$ is in $C_k$. In our example, we take $v_1 = v_3 = \text{false}, v_2 = v_4 = \text{true}$. Clearly
the formula is true for a given set of boolean values of variables if the transition
$t_{s_1}$ is live and the same for the reachability of a marking with one token in $p_s$.

Thus, there is still an open problem for $\Pi$-nets since the upper bound of
complexity for general Petri nets is in PSPACE. By contrast, the next proposition
provides an exact characterization of the complexity of the problems for (1-safe)
$\Pi$-nets. This distinctive result strengthens the specific character of the $\Pi$-nets
class.

**Proposition 5.** (1) The liveness and the reachability problems for 1-safe $\Pi$-
nets are PSPACE-complete.

(2) The reachability problem for $\Pi$-nets is EXPSPACE-complete.
Proof. Due to lack of space, we only address the claim (2). For symmetric nets systems, we know [5, 18] that the reachability problem is EXPSPACE complete. A net is symmetric iff for every transition \( t \), there is a "reverse" transition \( t' \) whose firing "undoes" the effect of the firing of \( t \), i.e., the input places of \( t \) are the output places of \( t' \) and vice versa. Symmetric nets are clearly \( H \)-nets. Thus, the reachability problem is EXPSPACE-hard for \( H \)-nets. But any \( H \)-net defines implicitly a symmetric net: for any transition \( t \), we may add a reverse transition \( t' \) without changing the resulting reachability graph, because the closed T-semiflows (without \( t \)) of transitions to which \( t \) belongs acts exactly as \( t' \) when fired in a cyclic way. Thus, the reachability problem for \( H \)-nets is reducible to the one for symmetric nets, hence in EXPSPACE, and finally EXPSPACE-complete.

4.3 Algebraic properties of PF-SPN

The availability of a product form equilibrium distribution allows the development of computational algorithms that are analogous to those developed for product form solution queueing networks (e.g. [3, 4, 21]). For instance proposals for algorithms for the computation of performance measures throughout the normalization constant calculus can be found in [7, 23]. In [1] a set of Arrival Theorems, similar to the analogous results developed for product form solution queueing networks [25] was proven, leading to a Mean Value Analysis (MVA) for the computation of performance measures for PF-SPNs. MVA for SPNs was also studied in [24].

This last section discusses reachability markings properties related to the solution of PF-SPN. For the development of computational algorithms for PF-SPN, the reachability set (RS) of the SPN must be partitioned according to certain criteria depending on the particular algorithm. For instance, the normalization constant computation algorithm requires a partitioning of the reachability set that groups together all the markings with a constant number of tokens in a given place. It is then important to know if reachable markings of a \( H \)-net system may be characterized, among all markings, by some specific criterion based on their value and structural elements of the net. The most common such criteria are the so-called state equation and the one based on the minimal P-semiflows of the net. The difficulty then lies in the quality of those criteria, i.e. whether they allow to select all reachable markings and, only reachable markings.

Let us recall that the state equation \( m = m_0 + C.\sigma \) is an algebraic equation that gives a necessary condition for a marking to be reachable. The set of vectors \( m \in \mathbb{N}^n \) such that \( \exists \sigma \in \mathbb{N}^m : m = m_0 + C.\sigma \) is called the Potential Reachability Set (PRS) of the net. Obviously, \( \text{RS}(m_0) \subseteq \text{PRS}(m_0) \). In the literature, there are several proposals of computational algorithms for PF-SPN. They use a reachability characterization based on the minimal P-semiflows. Therefore, another set of "potential" markings has been defined. Let \( B \) be the matrix whose rows are the set of minimal P-semiflows of the net. The Potential Reachability Set with respect to \( B \) is the set \( \text{PRS}^B(m_0) = \{ m \mid B.m = B.m_0 \} \). Clearly, \( \text{PRS}(m_0) \subseteq \text{PRS}^B(m_0) \) since \( B.C = 0 \).
An unreachable marking belonging to one of these PRS is called a spurious marking (see [27] for a detailed study of several kinds of PRS). We show below that, unfortunately, none of these two characterizations is able to capture all the peculiarities of PF-SPN, that is to say that there are II-net with spurious markings for PRS (thus for PRS$^B$).

First we may have $\text{PRS}(\mathbf{m}_0) \neq \text{PRS}^B(\mathbf{m}_0)$ in II-systems. This happens even in such simple case as the II-cycle of Figure 4(a): the dead marking $\mathbf{m}_1 = [1, 1]^T$ has the same dot-product with the P-semiflow $\mathbf{Y} = [1, 1]^T$ as the live one $\mathbf{m}_0 = [2, 0]$ although there is no $\sigma \in N^{|\mathbf{m}_0|}$ satisfying the state equation $\mathbf{m}_1 = \mathbf{m}_0 + \mathbf{C} \cdot \sigma$.

For what concerns the characterization of the reachability set of a II-net in terms of potential reachability set, the proposition below (we omit the proof for sake of place) provides a rather positive result, but we give next, two examples which prove that properties of II-nets are not strong enough to prevent the existence of spurious markings.

**Proposition 6.** With respect to the state equation,
(1) The potential reachability graph of $(\mathcal{N}, \mathbf{m}_0)$ is equal to the reverse of the potential reachability graph of $(\mathcal{N}^{-1}, \mathbf{m}_0)$.
(2) Spurious markings (if they exist) cannot be transient, i.e., if $\mathbf{m} \in \text{PRS}(\mathbf{m}_0) \setminus \text{RS}(\mathbf{m}_0)$, then there is no firing sequence $\sigma$ such that $\mathbf{m}[\sigma] \mathbf{m}'$ with $\mathbf{m}' \in \text{RS}(\mathbf{m}_0)$.

The net of Figure 4(b) gives the first negative result. For the unbounded II-net it is possible to see that $\mathbf{m} = [0, 0, 0]$ is a spurious marking. We can see that for any initial marking $\mathbf{m}_0 = [k_1, k_2, k_3]$, $\mathbf{m}_0\{t_1^{k_1}\} \mathbf{m}_1 = [0, k_1 + k_2, k_1 + k_3][t_2^{k_1+k_2}] \mathbf{m}_2 = [0, 0, 2k_1 + k_2 + k_3]$. Setting $k = 2k_1 + k_2 + k_3$ we have $\mathbf{m}_2\{t_3t_2^{k-1}\} \mathbf{m}_3 = [0, 0, 1]$. Now "firing" $t_2t_3$ the null marking is spuriously reached.

The net of Figure 4(c) gives another and definitive negative result. This II-net is bounded but it is possible to see that $\mathbf{m} = [0, 0, 1, 0, 1]$ is a spurious marking. Indeed, from the initial marking $\mathbf{m}_0 = [0, 1, 0, 0, 1]$ and with the "firing" of $t_2$ we obtain the marking $[0, 0, 1, 0, 1]$ that it is not a reachable marking. Hence we have $\mathbf{m} \in \text{PRS}(\mathbf{m}_0)$ but $\mathbf{m} \not\in \text{RS}(\mathbf{m}_0)$.

**Fig. 4.** II-net and potential reachability: (a) $\text{PRS}(\mathbf{m}_0) \neq \text{PRS}^B(\mathbf{m}_0)$, unbounded (b) and bounded (c) II-systems with spurious marking.
5 Conclusion

SPN with PF solution have been introduced some years ago as an extension of closed form solution methods of QN to SPN which allow to model systems with more complex synchronization schemes. In this paper we have presented four groups of new results giving a better insight in PF-SPN and allowing an efficient handling of this class of nets. We have first established a polynomial-time algorithm to check if a given SPN is a PF-SPN. This is an interesting result, in contrast with the general computation of T-semiflows which may produce an exponential number of T-semiflows (with respect to the size of the net). Then, we have proven a rate independent structural characterization of PF-SPN, which can also be checked in polynomial time. We call $\mathcal{P}$-nets the subclass of $\Pi$-nets satisfying this criterion. Moreover, for $\Pi$-nets, we are able to define transition rates globally dependent of components of the net "not related with" the considered transition, so that we can model complex dependency of activities on some other ones. Third, we have investigated untimed properties for the class of PF-SPN. We have shown that $\Pi$-nets, and even $\mathcal{P}$-nets do not fit in any standard class of PN. Nevertheless, we have proved specific properties for deadlock-freeness, liveness and reverse nets for $\Pi$-nets. For what concerns liveness/reachability in $\Pi$-nets and $\mathcal{P}$-nets, we were able to somewhat refine complexity bounds known for general PN. Finally, with examples and one proposition, we have given some answers, both positive and negative, to the problem of potential reachability, i.e. reachability based upon structural properties of the net. The interested reader will find detailed proofs and full versions of results in [10].
